3. Network Enumeration with Nmap

Enumeration

Enumeration is the most critical part of all. The art, the difficulty, and the goal are not to gain access to our target computer. Instead, it is identifying all of the ways we could attack a target we must find.

It is not just based on the tools we use. They will only do much good if we know what to do with the information we get from them. The tools are just tools, and tools alone should never replace our knowledge and our attention to detail. Here it is much more about actively interacting with the individual services to see what information they provide us and what possibilities they offer us.

It is essential to understand how these services work and what syntax they use for effective communication and interaction with the different services.

This phase aims to improve our knowledge and understanding of the technologies, protocols, and how they work and learn to deal with new information and adapt to our already acquired knowledge. Enumeration is collecting as much information as possible. The more information we have, the easier it will be for us to find vectors of attack.

Imagine the following situation:

Our partner is not at home and has misplaced our car keys. We call our partner and ask where the keys are. If we get an answer like "in the living room," it is entirely unclear and can take much time to find them there. However, what if our partner tells us something like "in the living room on the white shelf, next to the TV, in the third drawer"? As a result, it will be much easier to find them.

It's not hard to get access to the target system once we know how to do it. Most of the ways we can get access we can narrow down to the following two points:

- Functions and/or resources that allow us to interact with the target and/or provide additional information.
- Information that provides us with even more important information to access our target.

When scanning and inspecting, we look exactly for these two possibilities. Most of the information we get comes from misconfigurations or neglect of security for the respective services. Misconfigurations are either the result of ignorance or a wrong security mindset.

For example, if the administrator only relies on the firewall, Group Policy Objects (GPOs), and continuous updates, it is often not enough to secure the network.

Enumeration is the key.

That's what most people say, and they are right. However, it is too often misunderstood. Most people understand that they haven't tried all the tools to get the information they need. Most of the time, however, it's not the tools we haven't tried, but rather the fact that we don't know how to interact with the service and what's relevant.

That's precisely the reason why so many people stay stuck in one spot and don't get ahead. Had these people invested a couple of hours learning more about the service, how it works, and what it is meant for, they would save a few hours or even days from reaching their goal and get access to the system.

Manual enumeration is a critical component. Many scanning tools simplify and accelerate the process. However, these cannot always bypass the security measures of the services. The easiest way to illustrate this is to use the following example:

Most scanning tools have a timeout set until they receive a response from the service. If this tool does not respond within a specific time, this service/port will be marked as closed, filtered, or unknown. In the last two cases, we will still be able to work with it. However, if a port is marked as closed and Nmap doesn't show it to us, we will be in a bad situation. This service/port may provide us with the opportunity to find a way to access the system. Therefore, this result can take much unnecessary time until we find it.

Introduction to Nmap

Network Mapper (Nmap) is an open-source network analysis and security auditing tool written in C, C++, Python, and Lua. It is designed to scan networks and identify which hosts are available on the network using raw packets, and services and applications, including the name and version, where possible. It can also identify the operating systems and versions of these hosts. Besides other features, Nmap also offers scanning capabilities that can determine if packet filters, firewalls, or intrusion detection systems (IDS) are configured as needed.

Use Cases

The tool is one of the most used tools by network administrators and IT security specialists. It is used to:

Audit the security aspects of networks

- Simulate penetration tests
- Check firewall and IDS settings and configurations
- Types of possible connections
- Network mapping
- Response analysis
- Identify open ports
- Vulnerability assessment as well.

Nmap Architecture

Nmap offers many different types of scans that can be used to obtain various results about our targets. Basically, Nmap can be divided into the following scanning techniques:

- Host discovery
- Port scanning
- Service enumeration and detection
- OS detection
- Scriptable interaction with the target service (Nmap Scripting Engine)

Syntax

The syntax for Nmap is fairly simple and looks like this:

```
nmap <scan types> <options> <target>
```

Scan Techniques

Nmap offers many different scanning techniques, making different types of connections and using differently structured packets to send.

Here we can see all the scanning techniques Nmap offers:

```
nmap --help

<SNIP>
SCAN TECHNIQUES:
-sS/sT/sA/sW/sM: TCP SYN/Connect()/ACK/Window/Maimon scans

SOURCE SOURCE SYN/Connect()/ACK/Window/Maimon scans
```

```
-sU: UDP Scan
-sN/sF/sX: TCP Null, FIN, and Xmas scans
--scanflags <flags>: Customize TCP scan flags
-sI <zombie host[:probeport]>: Idle scan
-sY/sZ: SCTP INIT/COOKIE-ECHO scans
-sO: IP protocol scan
-b <FTP relay host>: FTP bounce scan
<SNIP>
```

For example, the TCP-SYN scan (-ss) is one of the default settings unless we have defined otherwise and is also one of the most popular scan methods. This scan method makes it possible to scan several thousand ports per second. The TCP-SYN scan sends one packet with the SYN flag and, therefore, never completes the three-way handshake, which results in not establishing a full TCP connection to the scanned port.

- If our target sends a SYN-ACK flagged packet back to us, Nmap detects that the port is open.
- If the target responds with an RST flagged packet, it is an indicator that the port is closed.
- If Nmap does not receive a packet back, it will display it as filtered. Depending on the firewall configuration, certain packets may be dropped or ignored by the firewall.

Let us take an example of such a scan.

```
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-11 22:50 UTC
Nmap scan report for localhost (127.0.0.1)
Host is up (0.000010s latency).
Not shown: 996 closed ports
PORT STATE SERVICE
22/tcp open ssh
80/tcp open http
5432/tcp open postgresql
5901/tcp open vnc-1

Nmap done: 1 IP address (1 host up) scanned in 0.18 seconds
```

In this example, we can see that we have four different TCP ports open. In the first column, we see the number of the port. Then, in the second column, we see the service's status and then what kind of service it is.

Host Discovery

When we need to conduct an internal penetration test for the entire network of a company, for example, then we should, first of all, get an overview of which systems are online that we can work with.

To actively discover such systems on the network, we can use various Nmap host discovery options. There are many options Nmap provides to determine whether our target is alive or not. The most effective host discovery method is to use **ICMP echo requests**, which we will look into.

It is always recommended to store every single scan. This can later be used for comparison, documentation, and reporting. After all, different tools may produce different results. Therefore it can be beneficial to distinguish which tool produces which results.

Scan Network Range

```
sudo nmap 10.129.2.0/24 -sn -oA tnet | grep for | cut -d" " -f5

10.129.2.4
10.129.2.10
10.129.2.11
10.129.2.18
10.129.2.20
10.129.2.28
```

Scanning Options	Description	
10.129.2.0/24	Target network range.	
-sn	Disables port scanning.	
-oA tnet	Stores the results in all formats starting with the name 'tnet'.	

This scanning method works only if the firewalls of the hosts allow it. Otherwise, we can use other scanning techniques to find out if the hosts are active or not. We will take a closer look at these techniques in " Firewall and IDS Evasion".

Scan IP List

During an internal penetration test, it is not uncommon for us to be provided with an IP list with the hosts we need to test. Nmap also gives us the option of working with lists and reading the hosts from this list instead of manually defining or typing them in.

Such a list could look something like this:

```
cat hosts.lst

10.129.2.4
10.129.2.10
10.129.2.11
10.129.2.18
10.129.2.19
10.129.2.20
10.129.2.28
```

If we use the same scanning technique on the predefined list, the command will look like this:

```
sudo nmap -sn -oA tnet -iL hosts.lst | grep for | cut -d" " -f5

10.129.2.18
10.129.2.19
10.129.2.20
```

Scanning Options	Description
-sn	Disables port scanning.
-oA tnet	Stores the results in all formats starting with the name 'tnet'.
-iL	Performs defined scans against targets in provided 'hosts.lst' list.

In this example, we see that only 3 of 7 hosts are active. Remember, this may mean that the other hosts ignore the default **ICMP echo requests** because of their firewall configurations. Since Nmap does not receive a response, it marks those hosts as inactive.

Scan Multiple IPs

It can also happen that we only need to scan a small part of a network. An alternative to the method we used last time is to specify multiple IP addresses.

```
sudo nmap -sn -oA tnet 10.129.2.18 10.129.2.19 10.129.2.20| grep for | cut
-d" " -f5
10.129.2.18
```

https://t.me/CyberFreeCourses

```
10.129.2.19
10.129.2.20
```

If these IP addresses are next to each other, we can also define the range in the respective octet.

```
sudo nmap -sn -oA tnet 10.129.2.18-20| grep for | cut -d" " -f5

10.129.2.18
10.129.2.19
10.129.2.20
```

Scan Single IP

Before we scan a single host for open ports and its services, we first have to determine if it is alive or not. For this, we can use the same method as before.

```
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-14 23:59 CEST Nmap scan report for 10.129.2.18 Host is up (0.087s latency).
MAC Address: DE:AD:00:00:BE:EF Nmap done: 1 IP address (1 host up) scanned in 0.11 seconds
```

Scanning Options	Description	
10.129.2.18	Performs defined scans against the target.	
-sn	Disables port scanning.	
-oA host	Stores the results in all formats starting with the name 'host'.	

If we disable port scan (-sn), Nmap automatically ping scan with ICMP Echo Requests (-PE). Once such a request is sent, we usually expect an ICMP reply if the pinging host is alive. The more interesting fact is that our previous scans did not do that because before Nmap could send an ICMP echo request, it would send an ARP ping resulting in an ARP reply. We can confirm this with the "--packet-trace" option. To ensure that ICMP echo requests are sent, we also define the option (-PE) for this.

```
sudo nmap 10.129.2.18 -sn -oA host -PE --packet-trace

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 00:08 CEST
SENT (0.0074s) ARP who-has 10.129.2.18 tell 10.10.14.2

RCVD (0.0309s) ARP reply 10.129.2.18 is-at DE:AD:00:00:BE:EF
Nmap scan report for 10.129.2.18
Host is up (0.023s latency).
MAC Address: DE:AD:00:00:BE:EF
Nmap done: 1 IP address (1 host up) scanned in 0.05 seconds
```

Scanning Options	Description
10.129.2.18	Performs defined scans against the target.
-sn	Disables port scanning.
-oA host	Stores the results in all formats starting with the name 'host'.
-PE	Performs the ping scan by using 'ICMP Echo requests' against the target.
packet-trace	Shows all packets sent and received

Another way to determine why Nmap has our target marked as "alive" is with the " -- reason " option.

```
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 00:10 CEST SENT (0.0074s) ARP who-has 10.129.2.18 tell 10.10.14.2 RCVD (0.0309s) ARP reply 10.129.2.18 is-at DE:AD:00:00:BE:EF Nmap scan report for 10.129.2.18 Host is up, received arp-response (0.028s latency). MAC Address: DE:AD:00:00:BE:EF Nmap done: 1 IP address (1 host up) scanned in 0.03 seconds
```

Scanning Options	Description	
10.129.2.18	Performs defined scans against the target.	
-sn	Disables port scanning.	
-oA host	Stores the results in all formats starting with the name 'host'.	

Scanning Options	Description
-PE	Performs the ping scan by using 'ICMP Echo requests' against the target.
reason	Displays the reason for specific result.

We see here that Nmap does indeed detect whether the host is alive or not through the ARP request and ARP reply alone. To disable ARP requests and scan our target with the desired ICMP echo requests, we can disable ARP pings by setting the "--disable-arp-ping" option. Then we can scan our target again and look at the packets sent and received.

```
sudo nmap 10.129.2.18 -sn -oA host -PE --packet-trace --disable-arp-ping

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 00:12 CEST
SENT (0.0107s) ICMP [10.10.14.2 > 10.129.2.18 Echo request (type=8/code=0)
id=13607 seq=0] IP [ttl=255 id=23541 iplen=28 ]

RCVD (0.0152s) ICMP [10.129.2.18 > 10.10.14.2 Echo reply (type=0/code=0)
id=13607 seq=0] IP [ttl=128 id=40622 iplen=28 ]

Nmap scan report for 10.129.2.18
Host is up (0.086s latency).
MAC Address: DE:AD:00:00:BE:EF
Nmap done: 1 IP address (1 host up) scanned in 0.11 seconds
```

We have already mentioned in the "Learning Process," and at the beginning of this module, it is essential to pay attention to details. An ICMP echo request can help us determine if our target is alive and identify its system. More strategies about host discovery can be found at:

https://nmap.org/book/host-discovery-strategies.html

Hint

Host and Port Scanning

It is essential to understand how the tool we use works and how it performs and processes the different functions. We will only understand the results if we know what they mean and how they are obtained. Therefore we will take a closer look at and analyze some of the scanning methods.

After we have found out that our target is alive, we want to get a more accurate picture of the system. The information we need includes:

- Open ports and its services
- Service versions
- Information that the services provided
- Operating system

There are a total of 6 different states for a scanned port we can obtain:

State	Description
open	This indicates that the connection to the scanned port has been established. These connections can be TCP connections , UDP datagrams as well as SCTP associations .
closed	When the port is shown as closed, the TCP protocol indicates that the packet we received back contains an RST flag. This scanning method can also be used to determine if our target is alive or not.
filtered	Nmap cannot correctly identify whether the scanned port is open or closed because either no response is returned from the target for the port or we get an error code from the target.
unfiltered	This state of a port only occurs during the TCP-ACK scan and means that the port is accessible, but it cannot be determined whether it is open or closed.
`open	filtered`
`closed	filtered`

By default, Nmap scans the top 1000 TCP ports with the SYN scan (-sS). This SYN scan is set only to default when we run it as root because of the socket permissions required to create raw TCP packets. Otherwise, the TCP scan (-sT) is performed by default. This means that if we do not define ports and scanning methods, these parameters are set automatically.

We can define the ports one by one (-p 22,25,80,139,445), by range (-p 22-445), by top ports (--top-ports=10) from the Nmap database that have been signed as most frequent, by scanning all ports (-p-) but also by defining a fast port scan, which contains top 100 ports (-F).

Scanning Top 10 TCP Ports

```
sudo nmap 10.129.2.28 --top-ports=10
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 15:36 CEST
Nmap scan report for 10.129.2.28
Host is up (0.021s latency).
P0RT
        STATE
                 SERVICE
21/tcp closed ftp
22/tcp open
                ssh
23/tcp closed telnet
25/tcp open smtp
80/tcp open
                 http
110/tcp open
                 pop3
139/tcp filtered netbios-ssn
443/tcp closed https
445/tcp filtered microsoft ds
3389/tcp closed ms-wbt-server
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)
Nmap done: 1 IP address (1 host up) scanned in 1.44 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
top-ports=10	Scans the specified top ports that have been defined as most frequent.

We see that we only scanned the top 10 TCP ports of our target, and Nmap displays their state accordingly. If we trace the packets Nmap sends, we will see the RST flag on TCP

port 21 that our target sends back to us. To have a clear view of the SYN scan, we disable the ICMP echo requests (-Pn), DNS resolution (-n), and ARP ping scan (--disable-arp-ping).

Nmap - Trace the Packets

```
sudo nmap 10.129.2.28 -p 21 --packet-trace -Pn -n --disable-arp-ping

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 15:39 CEST
SENT (0.0429s) TCP 10.10.14.2:63090 > 10.129.2.28:21 S ttl=56 id=57322
iplen=44 seq=1699105818 win=1024 <mss 1460 >
RCVD (0.0573s) TCP 10.129.2.28:21 > 10.10.14.2:63090 RA ttl=64 id=0
iplen=40 seq=0 win=0
Nmap scan report for 10.11.1.28
Host is up (0.014s latency).

PORT STATE SERVICE
21/tcp closed ftp
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)

Nmap done: 1 IP address (1 host up) scanned in 0.07 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-p 21	Scans only the specified port.
packet-trace	Shows all packets sent and received.
-n	Disables DNS resolution.
disable-arp-ping	Disables ARP ping.

We can see from the SENT line that we (10.10.14.2) sent a TCP packet with the SYN flag (S) to our target (10.129.2.28). In the next RCVD line, we can see that the target responds with a TCP packet containing the RST and ACK flags (RA). RST and ACK flags are used to acknowledge receipt of the TCP packet (ACK) and to end the TCP session (RST).

Request

Message	Description
SENT (0.0429s)	Indicates the SENT operation of Nmap, which sends a packet to the target.
TCP	Shows the protocol that is being used to interact with the target port.
10.10.14.2:63090 >	Represents our IPv4 address and the source port, which will be used by Nmap to send the packets.
10.129.2.28:21	Shows the target IPv4 address and the target port.
S	SYN flag of the sent TCP packet.
ttl=56 id=57322 iplen=44 seq=1699105818 win=1024 mss 1460	Additional TCP Header parameters.

Response

Message	Description
RCVD (0.0573s)	Indicates a received packet from the target.
TCP	Shows the protocol that is being used.
10.129.2.28:21 >	Represents targets IPv4 address and the source port, which will be used to reply.
10.10.14.2:63090	Shows our IPv4 address and the port that will be replied to.
RA	RST and ACK flags of the sent TCP packet.
ttl=64 id=0 iplen=40 seq=0 win=0	Additional TCP Header parameters.

Connect Scan

The Nmap <u>TCP Connect Scan</u> (-sT) uses the TCP three-way handshake to determine if a specific port on a target host is open or closed. The scan sends an SYN packet to the target port and waits for a response. It is considered open if the target port responds with an SYN-ACK packet and closed if it responds with an RST packet.

The Connect scan (also known as a full TCP connect scan) is highly accurate because it completes the three-way TCP handshake, allowing us to determine the exact state of a port (open, closed, or filtered). However, it is not the most stealthy. In fact, the Connect scan is one of the least stealthy techniques, as it fully establishes a connection, which creates logs on most systems and is easily detected by modern IDS/IPS solutions. That said, the Connect scan can still be useful in certain situations, particularly when accuracy is a priority, and the

https://t.me/CyberFreeCourses

goal is to map the network without causing significant disruption to services. Since the scan fully establishes a TCP connection, it interacts cleanly with services, making it less likely to cause service errors or instability compared to more intrusive scans. While it is not the most stealthy method, it is sometimes considered a more "polite" scan because it behaves like a normal client connection, thus having minimal impact on the target services.

It is also useful when the target host has a personal firewall that drops incoming packets but allows outgoing packets. In this case, a Connect scan can bypass the firewall and accurately determine the state of the target ports. However, it is important to note that the Connect scan is slower than other types of scans because it requires the scanner to wait for a response from the target after each packet it sends, which could take some time if the target is busy or unresponsive.

Scans like the SYN scan (also known as a half-open scan) are generally considered more stealthy because they do not complete the full handshake, leaving the connection incomplete after sending the initial SYN packet. This minimizes the chance of triggering connection logs while still gathering port state information. Advanced IDS/IPS systems, however, have adapted to detect even these subtler techniques.

Connect Scan on TCP Port 443

```
sudo nmap 10.129.2.28 -p 443 --packet-trace --disable-arp-ping -Pn -n --
reason -sT

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 16:26 CET
CONN (0.0385s) TCP localhost > 10.129.2.28:443 => Operation now in
progress
CONN (0.0396s) TCP localhost > 10.129.2.28:443 => Connected
Nmap scan report for 10.129.2.28
Host is up, received user-set (0.013s latency).

PORT STATE SERVICE REASON
443/tcp open https syn-ack
Nmap done: 1 IP address (1 host up) scanned in 0.04 seconds
```

Filtered Ports

When a port is shown as filtered, it can have several reasons. In most cases, firewalls have certain rules set to handle specific connections. The packets can either be dropped, or rejected.

When a packet gets dropped, Nmap receives no response from our target, and by default,

the retry rate (--max-retries) is set to 10. This means Nmap will resend the request to the target port to determine if the previous packet was accidentally mishandled or not.

Let us look at an example where the firewall drops the TCP packets we send for the port scan. Therefore we scan the TCP port **139**, which was already shown as filtered. To be able to track how our sent packets are handled, we deactivate the ICMP echo requests (-Pn), DNS resolution (-n), and ARP ping scan (--disable-arp-ping) again.

```
sudo nmap 10.129.2.28 -p 139 --packet-trace -n --disable-arp-ping -Pn

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 15:45 CEST
SENT (0.0381s) TCP 10.10.14.2:60277 > 10.129.2.28:139 S ttl=47 id=14523
iplen=44 seq=4175236769 win=1024 <mss 1460>
SENT (1.0411s) TCP 10.10.14.2:60278 > 10.129.2.28:139 S ttl=45 id=7372

Nmap scan report for 10.129.2.28
Host is up.

PORT STATE SERVICE
139/tcp filtered netbios-ssn
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)
Nmap done: 1 IP address (1 host up) scanned in 2.06 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-р 139	Scans only the specified port.
packet-trace	Shows all packets sent and received.
-n	Disables DNS resolution.
disable-arp-ping	Disables ARP ping.
-Pn	Disables ICMP Echo requests.

We see in the last scan that Nmap sent two TCP packets with the SYN flag. By the duration (2.06s) of the scan, we can recognize that it took much longer than the previous ones (~0.05s).

The case is different if the firewall rejects the packets. For this, we look at TCP port 445, which is handled accordingly by such a rule of the firewall.

```
sudo nmap 10.129.2.28 -p 445 --packet-trace -n --disable-arp-ping -Pn
```

```
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 15:55 CEST

SENT (0.0388s) TCP 10.129.2.28:52472 > 10.129.2.28:445 S ttl=49 id=21763

RCVD (0.0487s) ICMP [10.129.2.28 > 10.129.2.28 Port 445 unreachable
(type=3/code=3) ] IP [ttl=64 id=20998 iplen=72 ]

Nmap scan report for 10.129.2.28
Host is up (0.0099s latency).

PORT STATE SERVICE
445/tcp filtered microsoft-ds
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)

Nmap done: 1 IP address (1 host up) scanned in 0.05 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-p 445	Scans only the specified port.
packet-trace	Shows all packets sent and received.
-n	Disables DNS resolution.
disable-arp-ping	Disables ARP ping.
-Pn	Disables ICMP Echo requests.

As a response, we receive an ICMP reply with type 3 and error code 3, which indicates that the desired port is unreachable. Nevertheless, if we know that the host is alive, we can strongly assume that the firewall on this port is rejecting the packets, and we will have to take a closer look at this port later.

Discovering Open UDP Ports

Some system administrators sometimes forget to filter the UDP ports in addition to the TCP ones. Since UDP is a stateless protocol and does not require a three-way handshake like TCP. We do not receive any acknowledgment. Consequently, the timeout is much longer, making the whole UDP scan (-sU) much slower than the TCP scan (-sS).

Let's look at an example of what a UDP scan (-sU) can look like and what results it gives us.

UDP Port Scan

```
sudo nmap 10.129.2.28 -F -sU

Səsənoəəəədədə/əm:

y//:sditu
```

```
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 16:01 CEST
Nmap scan report for 10.129.2.28
Host is up (0.059s latency).
Not shown: 95 closed ports
PORT STATE SERVICE
68/udp open|filtered dhcpc
137/udp open netbios-ns
138/udp open|filtered netbios-dgm
631/udp open|filtered ipp
5353/udp open zeroconf
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)

Nmap done: 1 IP address (1 host up) scanned in 98.07 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-F	Scans top 100 ports.
-sU	Performs a UDP scan.

Another disadvantage of this is that we often do not get a response back because Nmap sends empty datagrams to the scanned UDP ports, and we do not receive any response. So we cannot determine if the UDP packet has arrived at all or not. If the UDP port is open, we only get a response if the application is configured to do so.

```
sudo nmap 10.129.2.28 -sU -Pn -n --disable-arp-ping --packet-trace -p 137
--reason

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 16:15 CEST

-sV	Performs a service scan.

More information about port scanning techniques we can find at: https://nmap.org/book/man-port-scanning-techniques.html

Saving the Results

Different Formats

While we run various scans, we should always save the results. We can use these later to examine the differences between the different scanning methods we have used.

Nmap can save the results in 3 different formats.

- Normal output (-oN) with the .nmap file extension
- Grepable output (-oG) with the .gnmap file extension
- \bullet XML output ($\,$ -oX) with the $\,$.xml $\,$ file extension

We can also specify the option (-oA) to save the results in all formats. The command could look like this:

https://t.me/CyberFreeCourses

Nmap done:	1 IP	address	(1	host	up)	scanned	in	10.22	seconds

Scanning Options	Description
10.129.2.28	Scans the specified target.
- p -	Scans all ports.
-oA target	Saves the results in all formats, starting the name of each file with 'target'.

If no full path is given, the results will be stored in the directory we are currently in. Next, we look at the different formats Nmap has created for us.

```
target.gnmap target.xml target.nmap
```

Normal Output

```
cat target.nmap

# Nmap 7.80 scan initiated Tue un 16 12:14:53 2020 as: nmap -p- -oA
target 10.129.2.28
Nmap scan report for 10.129.2.28

Style sheets

With the XML output, we can easily create HTML reports that are easy to read, even for non-technical people. This is later very useful for documentation, as it presents our results in a detailed and clear way.

To convert the stored results from XML format to HTML, we can use the tool xsltproc.

```
xsltproc target.xml -o target.html
```

If we now open the HTML file in our browser, we see a clear and structured presentation of our results.

More information about the output formats can be found at:

https://nmap.org/book/output.html

Service Enumeration

For us, it is essential to determine the application and its version as accurately as possible. We can use this information to scan for known vulnerabilities and analyze the source code

for that version if we find it. An exact version number allows us to search for a more precise exploit that fits the service and the operating system of our target.

Service Version Detection

It is recommended to perform a quick port scan first, which gives us a small overview of the available ports. This causes significantly less traffic, which is advantageous for us because otherwise we can be discovered and blocked by the security mechanisms. We can deal with these first and run a port scan in the background, which shows all open ports (-p-). We can use the version scan to scan the specific ports for services and their versions (-sv).

A full port scan takes quite a long time. To view the scan status, we can press the [Space Bar] during the scan, which will cause Nmap to show us the scan status.

```
sudo nmap 10.129.2.28 -p- -sV

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 19:44 CEST
[Space Bar]
Stats: 0:00:03 elapsed; 0 hosts completed (1 up), 1 undergoing SYN Stealth
Scan
SYN Stealth Scan Timing: About 3.64% done; ETC: 19:45 (0:00:53 remaining)
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
- p -	Scans all ports.
-sV	Performs service version detection on specified ports.

Another option (--stats-every=5s) that we can use is defining how periods of time the status should be shown. Here we can specify the number of seconds (s) or minutes (m), after which we want to get the status.

```
sudo nmap 10.129.2.28 -p- -sV --stats-every=5s

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 19:46 CEST
Stats: 0:00:05 elapsed; 0 hosts completed (1 up), 1 undergoing SYN Stealth
Scan
SYN Stealth Scan Timing: About 13.91% done; ETC: 19:49 (0:00:31 remaining)

SOSJNO OOJAJJJOQAO/OWIJ//:Sdlju
```

```
Stats: 0:00:10 elapsed; 0 hosts completed (1 up), 1 undergoing SYN Stealth Scan
SYN Stealth Scan Timing: About 39.57% done; ETC: 19:48 (0:00:15 remaining)
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
- p -	Scans all ports.
-sV	Performs service version detection on specified ports.
stats-every=5s	Shows the progress of the scan every 5 seconds.

We can also increase the verbosity level (-v / -vv), which will show us the open ports directly when Nmap detects them.

```
sudo nmap 10.129.2.28 -p- -sV -v
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-15 20:03 CEST

```

Scanning Options	Description
10.129.2.28	Scans the specified target.
- p -	Scans all ports.
-sV	Performs service version detection on specified ports.

Primarily, Nmap looks at the banners of the scanned ports and prints them out. If it cannot identify versions through the banners, Nmap attempts to identify them through a signature-based matching system, but this significantly increases the scan's duration. One disadvantage to Nmap 's presented results is that the automatic scan can miss some information because sometimes Nmap does not know how to handle it. Let us look at an example of this.

```
sudo nmap 10.129.2.28 -p- -sV -Pn -n --disable-arp-ping --packet-trace
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-16 20:10 CEST
<SNIP>
NSOCK INFO [0.4200s] nsock trace handler callback(): Callback: READ

Service Info: Host: inlane
Service detection performed. Please report any incorrect results at
https://nmap.org/submit/ .
Nmap done: 1 IP address (1 host up) scanned in 0.47 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
- p -	Scans all ports.
-sV	Performs service version detection on specified ports.
-Pn	Disables ICMP Echo requests.
-n	Disables DNS resolution.
disable-arp-ping	Disables ARP ping.
packet-trace	Shows all packets sent and received.

If we look at the results from Nmap, we can see the port's status, service name, and hostname. Nevertheless, let us look at this line here:

• NSOCK INFO [0.4200s] nsock_trace_handler_callback(): Callback: READ SUCCESS for EID 18 [10.129.2.28:25] (35 bytes): 220 inlane ESMTP Postfix (Ubuntu)..

Then we see that the SMTP server on our target gave us more information than <code>Nmap</code> showed us. Because here, we see that it is the Linux distribution <code>Ubuntu</code>. It happens because, after a successful three-way handshake, the server often sends a banner for identification. This serves to let the client know which service it is working with. At the network level, this happens with a <code>PSH</code> flag in the TCP header. However, it can happen that some services do not immediately provide such information. It is also possible to remove or manipulate the banners from the respective services. If we <code>manually</code> connect to the SMTP server using <code>nc</code>, grab the banner, and intercept the network traffic using <code>tcpdump</code>, we can see what <code>Nmap</code> did not show us.

Tcpdump

```
sudo tcpdump -i eth0 host 10.10.14.2 and 10.129.2.28

tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on eth0, link-type EN10MB (Ethernet), capture size 262144 bytes
```

Nc

```
nc -nv 10.129.2.28 25

Connection to 10.129.2.28 port 25 [tcp/*] succeeded!

220 inlane ESMTP Postfix (Ubuntu)
```

Tcpdump - Intercepted Traffic

```

```

```
win 2058, options [nop,nop,TS val 331260368 ecr 1800383985], length 0
```

The first three lines show us the three-way handshake.

1.	[SYN]	18:28:07.128564 IP 10.10.14.2.59618 > 10.129.2.28.smtp: Flags [S], <snip></snip>
2.	[SYN- ACK]	18:28:07.255151 IP 10.129.2.28.smtp > 10.10.14.2.59618: Flags [S.], <snip></snip>
3.	[ACK]	18:28:07.255281 IP 10.10.14.2.59618 > 10.129.2.28.smtp: Flags [.], <snip></snip>

After that, the target SMTP server sends us a TCP packet with the PSH and ACK flags, where PSH states that the target server is sending data to us and with ACK simultaneously informs us that all required data has been sent.

4.	[PSH-	18:28:07.319306 IP 10.129.2.28.smtp > 10.10.14.2.59618:
	ACK]	Flags [P.], <snip></snip>

The last TCP packet that we sent confirms the receipt of the data with an ACK.

		() ^v	
5.	[ACK]	18:28:07.319426 JP 10.10.14.2.59618 > 10.129.2.28.smtp:	
		Flags [.], SNIP>	

Nmap Scripting Engine

Nmap Scripting Engine (NSE) is another handy feature of Nmap . It provides us with the possibility to create scripts in Lua for interaction with certain services. There are a total of 14 categories into which these scripts can be divided:

Category	Description
auth	Determination of authentication credentials.
broadcast	Scripts, which are used for host discovery by broadcasting and the discovered hosts, can be automatically added to the remaining scans.
brute	Executes scripts that try to log in to the respective service by brute-forcing with credentials.

Category	Description
default	Default scripts executed by using the -sc option.
discovery	Evaluation of accessible services.
dos	These scripts are used to check services for denial of service vulnerabilities and are used less as it harms the services.
exploit	This category of scripts tries to exploit known vulnerabilities for the scanned port.
external	Scripts that use external services for further processing.
fuzzer	This uses scripts to identify vulnerabilities and unexpected packet handling by sending different fields, which can take much time.
intrusive	Intrusive scripts that could negatively affect the target system.
malware	Checks if some malware infects the target system.
safe	Defensive scripts that do not perform intrusive and destructive access.
version	Extension for service detection.
vuln	Identification of specific vulnerabilities.

We have several ways to define the desired scripts in Nmap .

Default Scripts

```
sudo nmap <target> -sC
```

Specific Scripts Category

```
sudo nmap <target> --script <category>
```

Defined Scripts

```
sudo nmap <target> --script <script-name>,<script-name>,...
```

For example, let us keep working with the target SMTP port and see the results we get with two defined scripts.

Nmap - Specifying Scripts

```
sudo nmap 10.129.2.28 -p 25 --script banner,smtp-commands

SƏSJNOJƏƏJ_JƏQÁJ/ƏW']//:Sd]
```

```
Starting Nmap 7.80 (https://nmap.org ) at 2020-06-16 23:21 CEST
Nmap scan report for 10.129.2.28
Host is up (0.050s latency).

PORT STATE SERVICE
25/tcp open smtp
|_banner: 220 inlane ESMTP Postfix (Ubuntu)
|_smtp-commands: inlane, PIPELINING, SIZE 10240000, VRFY, ETRN, STARTTLS,
ENHANCEDSTATUSCODES, 8BITMIME, DSN, SMTPUTF8,
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-p 25	Scans only the specified port.
script banner,smtp-commands	Uses specified NSE scripts.

We see that we can recognize the **Ubuntu** distribution of Linux by using the' banner' script. The smtp-commands script shows us which commands we can use by interacting with the target SMTP server. In this example, such information may help us to find out existing users on the target. Nmap also gives us the ability to scan our target with the aggressive option (- A). This scans the target with multiple options as service detection (-sV), OS detection (- traceroute (--traceroute), and with the default NSE scripts (-sC).

Nmap - Aggressive Scan

```
sudo nmap 10.129.2.28 -p 80 -A
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-17 01:38 CEST
Nmap scan report for 10.129.2.28
Host is up (0.012s latency).

                               https://vulners.com/cve/CVE-2017-15715
<SNIP>
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-p 80	Scans only the specified port.
-sV	Performs service version detection on specified ports.
script vuln	Uses all related scripts from specified category.

The scripts used for the last scan interact with the webserver and its web application to find out more information about their versions and check various databases to see if there are known vulnerabilities. More information about NSE scripts and the corresponding categories we can find at: https://nmap.org/nsedoc/index.html

Performance

Scanning performance plays a significant role when we need to scan an extensive network or are dealing with low network bandwidth. We can use various options to tell Nmap how fast (-T <0-5>), with which frequency (--min-parallelism <number>), which timeouts (--max-rtt-timeout <time>) the test packets should have, how many packets should be sent simultaneously (--min-rate <number>), and with the number of retries (--max-retries <number>) for the scanned ports the targets should be scanned.

Timeouts

When Nmap sends a packet, it takes some time (Round-Trip-Time - RTT) to receive a response from the scanned port. Generally, Nmap starts with a high timeout (--min-RTT-timeout) of 100ms. Let us look at an example by scanning the whole network with 256 hosts, including the top 100 ports.

Default Scan

```
sudo nmap 10.129.2.0/24 -F

<SNIP>
Nmap done: 256 IP addresses (10 hosts up) scanned in 39.44 seconds
```

Optimized RTT

```
sudo nmap 10.129.2.0/24 -F --initial-rtt-timeout 50ms --max-rtt-timeout
100ms

<SNIP>
Nmap done: 256 IP addresses (8 hosts up) scanned in 12.29 seconds
```

Scanning Options	Description
10.129.2.0/24	Scans the specified target network.
-F	Scans top 100 ports.
initial-rtt-timeout 50ms	Sets the specified time value as initial RTT timeout.
max-rtt-timeout 100ms	Sets the specified time value as maximum RTT timeout.

When comparing the two scans, we can see that we found two hosts less with the optimized scan, but the scan took only a quarter of the time. From this, we can conclude that setting the initial RTT timeout (--initial-rtt-timeout) to too short a time period may cause us to overlook hosts.

Max Retries

Another way to increase scan speed is by specifying the retry rate of sent packets (--max-retries). The default value is 10, but we can reduce it to 0. This means if Nmap does not receive a response for a port, it won't send any more packets to that port and will skip it.

Default Scan

```
sudo nmap 10.129.2.0/24 -F | grep "/tcp" | wc -l
23
```

Reduced Retries

```
sudo nmap 10.129.2.0/24 -F --max-retries 0 | grep "/tcp" | wc -l
21
```

Scanning Options	Description
10.129.2.0/24	Scans the specified target network.
- F	Scans top 100 ports.
max-retries 0	Sets the number of retries that will be performed during the scan.

Again, we recognize that accelerating can also have a negative effect on our results, which means we can overlook important information.

Rates

During a white-box penetration test, we may get whitelisted for the security systems to check the systems in the network for vulnerabilities and not only test the protection measures. If we know the network bandwidth, we can work with the rate of packets sent, which significantly speeds up our scans with Nmap. When setting the minimum rate (--min-rate <number>) for sending packets, we tell Nmap to simultaneously send the specified number of packets. It will attempt to maintain the rate accordingly.

Default Scan

```
sudo nmap 10.129.2.0/24 -F -oN tnet.default
<SNIP>
Nmap done: 256 IP addresses (10 hosts up) scanned in 29.83 seconds
```

Optimized Scan

```
sudo nmap 10.129.2.0/24 -F -oN tnet.minrate300 --min-rate 300

<SNIP>
Nmap done: 256 IP addresses (10 hosts up) scanned in 8.67 seconds
```

Scanning Options	Description
10.129.2.0/24	Scans the specified target network.
- F	Scans top 100 ports.
-oN tnet.minrate300	Saves the results in normal formats, starting the specified file name.
min-rate 300	Sets the minimum number of packets to be sent per second.

Default Scan - Found Open Ports

```
cat tnet.default | grep "/tcp" | wc -l
23
```

Optimized Scan - Found Open Ports

```
cat tnet.minrate300 | grep "/tcp" | wc -l
23
```

Timing

Because such settings cannot always be optimized manually, as in a black-box penetration test, Nmap offers six different timing templates (-T < 0-5 >) for us to use. These values (0-5) determine the aggressiveness of our scans. This can also have negative effects if the scan is too aggressive, and security systems may block us due to the produced network traffic. The default timing template used when we have defined nothing else is the normal (-T > 3).

• -T 0 / -T paranoid

```
-T 1 / -T sneaky
-T 2 / -T polite
-T 3 / -T normal
-T 4 / -T aggressive
-T 5 / -T insane
```

These templates contain options that we can also set manually, and have seen some of them already. The developers determined the values set for these templates according to their best results, making it easier for us to adapt our scans to the corresponding network environment. The exact used options with their values we can find here:

https://nmap.org/book/performance-timing-templates.html

Default Scan

```
sudo nmap 10.129.2.0/24 -F -oN tnet.default

<SNIP>
Nmap done: 256 IP addresses (10 hosts up) scanned in 32.44 seconds
```

Insane Scan

```
sudo nmap 10.129.2.0/24 -F -oN tnet T5 -T 5

<SNIP>
Nmap done: 256 IP addresses (10 hosts up) scanned in 18.07 seconds
```

Scanning Options	Description
10.129.2.0/24	Scans the specified target network.
- F	Scans top 100 ports.
-oN tnet.T5	Saves the results in normal formats, starting the specified file name.
-T 5	Specifies the insane timing template.

Default Scan - Found Open Ports

```
cat tnet.default | grep "/tcp" | wc -l
```

Insane Scan - Found Open Ports

```
cat tnet.T5 | grep "/tcp" | wc -l
23
```

More information about scan performance we can find at https://nmap.org/book/man-performance.html

Firewall and IDS/IPS Evasion

Nmap gives us many different ways to bypass firewalls rules and IDS/IPS. These methods include the fragmentation of packets, the use of decoys, and others that we will discuss in this section.

Firewalls

A firewall is a security measure against unauthorized connection attempts from external networks. Every firewall security system is based on a software component that monitors network traffic between the firewall and incoming data connections and decides how to handle the connection based on the rules that have been set. It checks whether individual network packets are being passed, ignored, or blocked. This mechanism is designed to prevent unwanted connections that could be potentially dangerous.

IDS/IPS

Like the firewall, the intrusion detection system (IDS) and intrusion prevention system (IPS) are also software-based components. IDS scans the network for potential attacks, analyzes them, and reports any detected attacks. IPS complements IDS by taking specific defensive measures if a potential attack should have been detected. The analysis of such attacks is based on pattern matching and signatures. If specific patterns are detected, such as a service detection scan, IPS may prevent the pending connection attempts.

Determine Firewalls and Their Rules

We already know that when a port is shown as filtered, it can have several reasons. In most cases, firewalls have certain rules set to handle specific connections. The packets can either be dropped, or rejected. The dropped packets are ignored, and no response is returned from the host.

This is different for rejected packets that are returned with an RST flag. These packets contain different types of ICMP error codes or contain nothing at all.

Such errors can be:

- Net Unreachable
- Net Prohibited
- Host Unreachable
- Host Prohibited
- Port Unreachable
- Proto Unreachable

Nmap's TCP ACK scan (-sA) method is much harder to filter for firewalls and IDS/IPS systems than regular SYN (-sS) or Connect scans (sT) because they only send a TCP packet with only the ACK flag. When a port is closed or open, the host must respond with an RST flag.

Unlike outgoing connections, all connection attempts (with the SYN flag) from external networks are usually blocked by firewalls. However, the packets with the ACK flag are often passed by the firewall because the firewall cannot determine whether the connection was first established from the external network or the internal network.

If we look at these scans, we will see how the results differ.

SYN-Scan

```
sudo nmap 10.129.2.28 -p 21,22,25 -sS -Pn -n --disable-arp-ping --packet-
trace

                 smtp
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)
Nmap done: 1 IP address (1 host up) scanned in 0.15 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-p 21,22,25	Scans only the specified ports.
-sS	Performs SYN scan on specified ports.
-sA	Performs ACK scan on specified ports.
-Pn	Disables ICMP Echo requests.
-n	Disables DNS resolution.
disable-arp-ping	Disables ARP ping.
packet-trace	Shows all packets sent and received.

Please pay attention to the RCVD packets and its set flag we receive from our target. With the SYN scan (-sS) our target tries to establish the TCP connection by sending a packet back with the SYN-ACK (SA) flags set and with the ACK scan (-sA) we get the RST flag because TCP port 22 is open. For the TCP port 25, we do not receive any packets back, which indicates that the packets will be dropped.

Detect IDS/IPS

Unlike firewalls and their rules, the detection of IDS/IPS systems is much more difficult because these are passive traffic monitoring systems. IDS systems examine all connections between hosts. If the IDS finds packets containing the defined contents or specifications, the administrator is notified and takes appropriate action in the worst case.

IPS systems take measures configured by the administrator independently to prevent potential attacks automatically. It is essential to know that IDS and IPS are different applications and that IPS serves as a complement to IDS.

Several virtual private servers (VPS) with different IP addresses are recommended to determine whether such systems are on the target network during a penetration test. If the administrator detects such a potential attack on the target network, the first step is to block the IP address from which the potential attack comes.

As a result, we will no longer be able to access the network using that IP address, and our Internet Service Provider (ISP) will be contacted and blocked from all access to the Internet.

• IDS systems alone are usually there to help administrators detect potential attacks on their network. They can then decide how to handle such connections. We can trigger certain security measures from an administrator, for example, by aggressively scanning

- a single port and its service. Based on whether specific security measures are taken, we can detect if the network has some monitoring applications or not.
- One method to determine whether such IPS system is present in the target network is
 to scan from a single host (VPS). If at any time this host is blocked and has no access
 to the target network, we know that the administrator has taken some security
 measures. Accordingly, we can continue our penetration test with another VPS.

Consequently, we know that we need to be quieter with our scans and, in the best case, disguise all interactions with the target network and its services.

Decoys

There are cases in which administrators block specific subnets from different regions in principle. This prevents any access to the target network. Another example is when IPS should block us. For this reason, the Decoy scanning method (-D) is the right choice. With this method, Nmap generates various random IP addresses inserted into the IP header to disguise the origin of the packet sent.

With this method, we can generate random (RND) a specific number (for example: 5) of IP addresses separated by a colon (:). Our real IP address is then randomly placed between the generated IP addresses. In the next example, our real IP address is therefore placed in the second position. Another critical point is that the decoys must be alive. Otherwise, the service on the target may be unreachable due to SYN-flooding security mechanisms.

Scan by Using Decoys

```

Nmap scan report for 10.129.2.28
```

https://t.me/CyberFreeCourses

```
Host is up (0.099s latency).

PORT STATE SERVICE
80/tcp open http
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)

Nmap done: 1 IP address (1 host up) scanned in 0.15 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-p 80	Scans only the specified ports.
-sS	Performs SYN scan on specified ports.
-Pn	Disables ICMP Echo requests.
-n	Disables DNS resolution.
disable-arp- ping	Disables ARP ping.
packet-trace	Shows all packets sent and received
-D RND:5	Generates five random IP addresses that indicates the source IP the connection comes from.

The spoofed packets are often filtered out by ISPs and routers, even though they come from the same network range. Therefore, we can also specify our VPS servers' IP addresses and use them in combination with " IP ID manipulation in the IP headers to scan the target.

Another scenario would be that only individual subnets would not have access to the server's specific services. So we can also manually specify the source IP address (-S) to test if we get better results with this one. Decoys can be used for SYN, ACK, ICMP scans, and OS detection scans. So let us look at such an example and determine which operating system it is most likely to be.

Testing Firewall Rule

```
sudo nmap 10.129.2.28 -n -Pn -p445 -0

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-22 01:23 CEST
Nmap scan report for 10.129.2.28
Host is up (0.032s latency).

PORT STATE SERVICE
445/tcp filtered microsoft-ds
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)
Too many fingerprints match this host to give specific OS details
```

https://t.me/CyberFreeCourses

```
Network Distance: 1 hop

OS detection performed. Please report any incorrect results at https://nmap.org/submit/ .

Nmap done: 1 IP address (1 host up) scanned in 3.14 seconds
```

Scan by Using Different Source IP

```
sudo nmap 10.129.2.28 -n -Pn -p 445 -0 -S 10.129.2.200 -e tun0
Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-22 01:16 CEST
Nmap scan report for 10.129.2.28
Host is up (0.010s latency).
PORT STATE SERVICE
445/tcp open microsoft-ds
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)
Warning: OSScan results may be unreliable because we could not find at
least 1 open and 1 closed port
Aggressive OS guesses: Linux 2.6.32 (96%), Linux 3.2 - 4.9 (96%), Linux
2.6.32 - 3.10 (96\%), Linux 3.4 - 3.10 (95\%), Linux 3.1 (95\%), Linux 3.2
(95%), AXIS 210A or 211 Network Camera (Linux 2.6.17) (94%), Synology
DiskStation Manager 5.2-5644 (94%), Linux 2.6.32 - 2.6.35 (94%), Linux
2.6.32 - 3.5 (94%)
No exact OS matches for host (test conditions non-ideal).
Network Distance: 1 hop
OS detection performed. Please report any incorrect results at
https://nmap.org/submit/ .
Nmap done: 1 IP address (1 host up) scanned in 4.11 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-n	Disables DNS resolution.
-Pn	Disables ICMP Echo requests.
-p 445	Scans only the specified ports.
-0	Performs operation system detection scan.
-S	Scans the target by using different source IP address.
10.129.2.200	Specifies the source IP address.
-e tun0	Sends all requests through the specified interface.

DNS Proxying

By default, Nmap performs a reverse DNS resolution unless otherwise specified to find more important information about our target. These DNS queries are also passed in most cases because the given web server is supposed to be found and visited. The DNS queries are made over the UDP port 53. The TCP port 53 was previously only used for the so-called "Zone transfers" between the DNS servers or data transfer larger than 512 bytes. More and more, this is changing due to IPv6 and DNSSEC expansions. These changes cause many DNS requests to be made via TCP port 53.

However, Nmap still gives us a way to specify DNS servers ourselves (--dns-server <ns>,<ns>). This method could be fundamental to us if we are in a demilitarized zone (DMZ). The company's DNS servers are usually more trusted than those from the Internet. So, for example, we could use them to interact with the hosts of the internal network. As another example, we can use TCP port 53 as a source port (--source-port) for our scans. If the administrator uses the firewall to control this port and does not filter IDS/IPS properly, our TCP packets will be trusted and passed through.

SYN-Scan of a Filtered Port

```
sudo nmap 10.129.2.28 -p50000 -sS -Pn -n --disable-arp-ping --packet-trace

Starting Nmap 7.80 ( https://nmap.org ) at 2020-06-21 22:50 CEST

SENT (0.0417s) TCP 10.10.14.2:33436 > 10.129.2.28:50000 S ttl=41 id=21939

```

```
iplen=44   seq=540635485 win=64240 <mss 1460>
Nmap scan report for 10.129.2.28
Host is up (0.013s latency).

PORT     STATE SERVICE
50000/tcp open ibm-db2
MAC Address: DE:AD:00:00:BE:EF (Intel Corporate)

Nmap done: 1 IP address (1 host up) scanned in 0.08 seconds
```

Scanning Options	Description
10.129.2.28	Scans the specified target.
-p 50000	Scans only the specified ports.
-sS	Performs SYN scan on specified ports.
-Pn	Disables ICMP Echo requests.
-n	Disables DNS resolution.
disable-arp-ping	Disables ARP ping.
packet-trace	Shows all packets sent and received.
source-port 53	Performs the scans from specified source port.

Now that we have found out that the firewall accepts TCP port 53, it is very likely that IDS/IPS filters might also be configured much weaker than others. We can test this by trying to connect to this port by using Netcat.

Connect To The Filtered Port

```
ncat -nv --source-port 53 10.129.2.28 50000

Ncat: Version 7.80 ( https://nmap.org/ncat )
Ncat: Connected to 10.129.2.28:50000.

220 ProFTPd
```

Firewall and IDS/IPS Evasion Labs

In the next three sections, we get different scenarios to practice where we have to scan our target. Firewall rules and IDS/IPS protect the systems, so we need to use the techniques

shown to bypass the firewall rules and do this as quiet as possible. Otherwise, we will be blocked by IPS.

Firewall and IDS/IPS Evasion - Easy Lab

Now let's get practical. A company hired us to test their IT security defenses, including their IDS and IPS systems. Our client wants to increase their IT security and will, therefore, make specific improvements to their IDS/IPS systems after each successful test. We do not know, however, according to which guidelines these changes will be made. Our goal is to find out specific information from the given situations.

We are only ever provided with a machine protected by IDS/IPS systems and can be tested. For learning purposes and to get a feel for how IDS/IPS can behave, we have access to a status web page at:

This page shows us the number of alerts. We know that if we receive a specific amount of alerts, we will be banned. Therefore we have to test the target system as quietly as possible.

Firewall and IDS/IPS Evasion - Medium Lab

After we conducted the first test and submitted our results to our client, the administrators made some changes and improvements to the IDS/IPS and firewall. We could hear that the administrators were not satisfied with their previous configurations during the meeting, and they could see that the network traffic could be filtered more strictly.

Firewall and IDS/IPS Evasion - Hard Lab

With our second test's help, our client was able to gain new insights and sent one of its administrators to a training course for IDS/IPS systems. As our client told us, the training would last one week. Now the administrator has taken all the necessary precautions and wants us to test this again because specific services must be changed, and the communication for the provided software had to be modified.
